

## Topics of today:

More about singular DCJ-indel distance and sorting:

1. Restricted DCJ-indel model
2. The diameter of the DCJ-indel distance
3. Establishing the triangular inequality

Capping

1. Capped relational graph of canonical genomes
2. Capped relational graph of singular genomes
3. Indel-potential of cycles via transitions

## Singular DCJ-indel model - summary

**DCJ-indel distance:**  $d_{\text{DCJ}}^{\text{ID}}(\mathbb{A}, \mathbb{B}) = n - |\mathcal{C}| - \frac{|\mathcal{P}_{\mathbb{A}\mathbb{B}}|}{2} + \sum_{C \in \mathcal{R}\mathcal{G}} \lambda(C) - \delta$ , where  $\delta$  is the value obtained by optimizing deducting path recombinations

$\mathbb{A}$  and  $\mathbb{B}$  are circular:  $d_{\text{DCJ}}^{\text{ID}}(\mathbb{A}, \mathbb{B}) = n - |\mathcal{C}| + \sum_{C \in \mathcal{R}\mathcal{G}} \lambda(C)$

Both distance computation and sorting can be done in **linear time**.

# Singular DCJ-indel sorting: trade-off between DCJ and indels

A sorting algorithm that maximizes gaining DCJs with  $\Delta_\lambda = 0$  minimizes indels.

However, these gaining DCJs can be often replaced by  $\begin{cases} \text{neutral DCJs with } \Delta_\lambda = -1 \\ \text{losing DCJs with } \Delta_\lambda = -2 \end{cases}$

⇓

There is a big range of sorting possibilities between

- a sorting algorithm that maximizes gaining DCJs with  $\Delta_\lambda = 0$  (minimizing indels)
- a sorting algorithm that minimizes gaining DCJs with  $\Delta_\lambda = 0$  (maximizing indels)

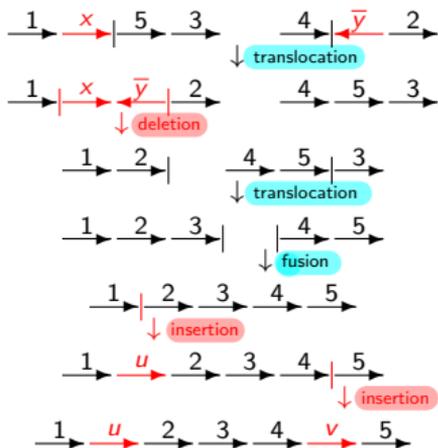

# Singular DCJ-indel sorting: trade-off between DCJ and indels

Two optimal scenarios sorting  $\{ [1 \times 5 3], [4 \bar{y} 2] \}$  into  $\{ [1 u 2 3 4 v 5] \}$

Maximizing  
gaining DCJs

(i)

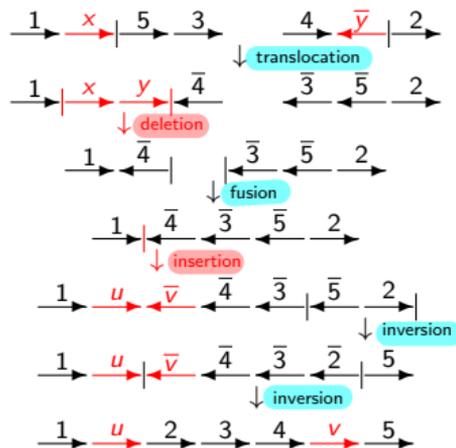

Minimizing DCJs gives 3 DCJs and 3 indels

Minimizing  
gaining DCJs

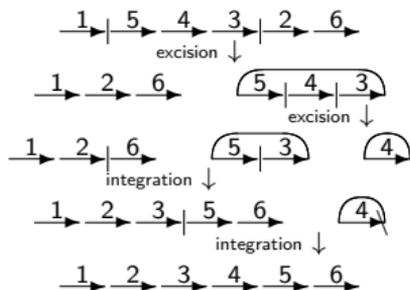

(ii)

Minimizing indels gives 4 DCJs and 2 indels

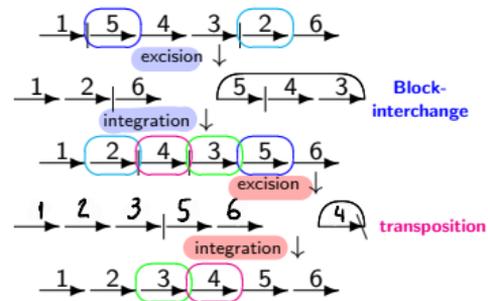

# DCJ model - circular excision/integration

## Canonical DCJ model

Many circular chromosomes can coexist in the intermediate genomes.

## Restricted canonical DCJ model

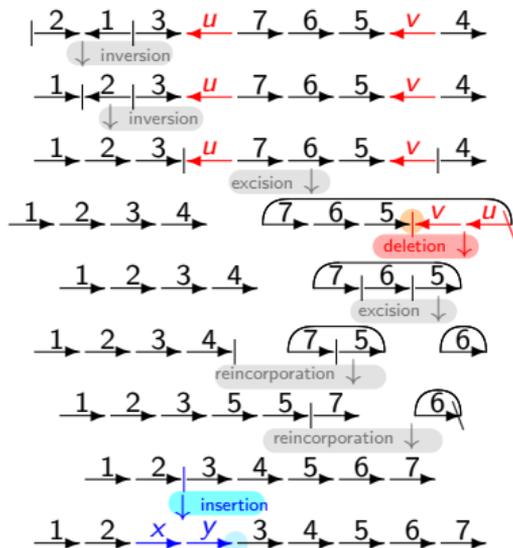

A circular chromosome is immediately reintegrated after its excision.

The DCJ distance is the same for both the general and the restricted DCJ models

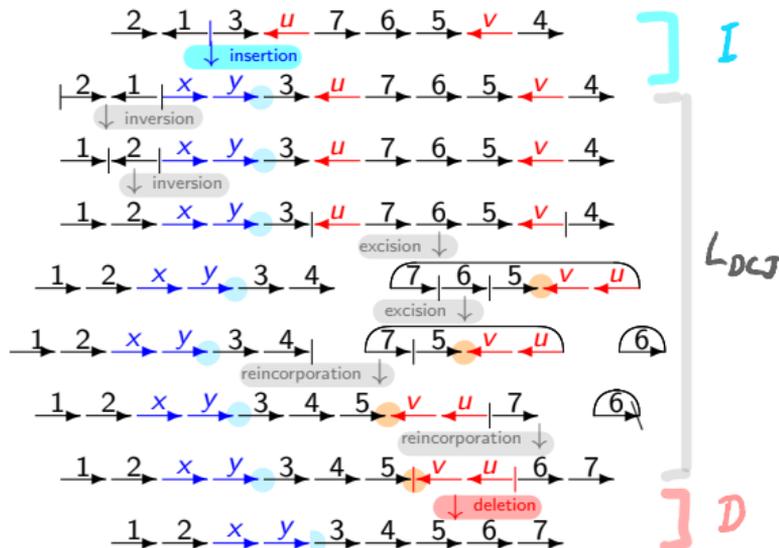

# Restricted DCJ-indel (singular linear genomes)

In any sorting sequence, it is always possible to  $\left\{ \begin{array}{l} \text{move deletions down} \\ \text{move insertions up} \end{array} \right.$

S: general DCJ-indel sorting

L: "layered" DCJ-indel sorting

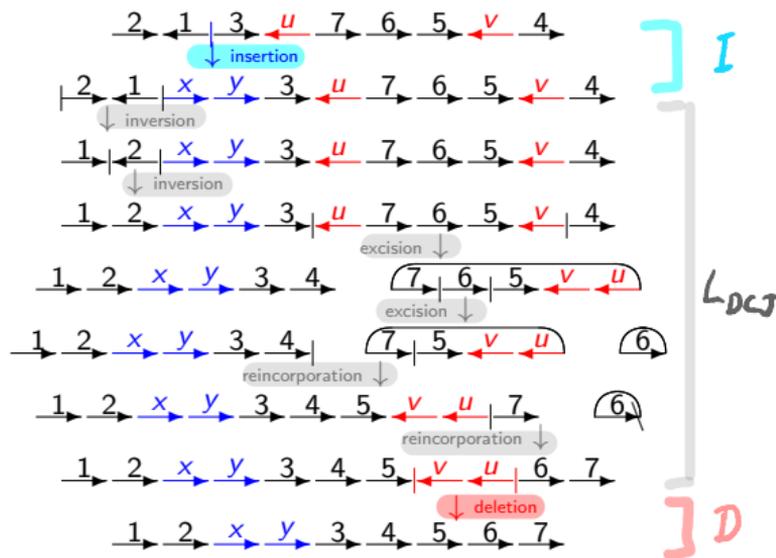

S : general sequence of DCJ and indel operations sorting linear  $\mathbb{A}$  into linear  $\mathbb{B}$

L : "layered" sequence of insertions, DCJs and deletions sorting linear  $\mathbb{A}$  into linear  $\mathbb{B}$

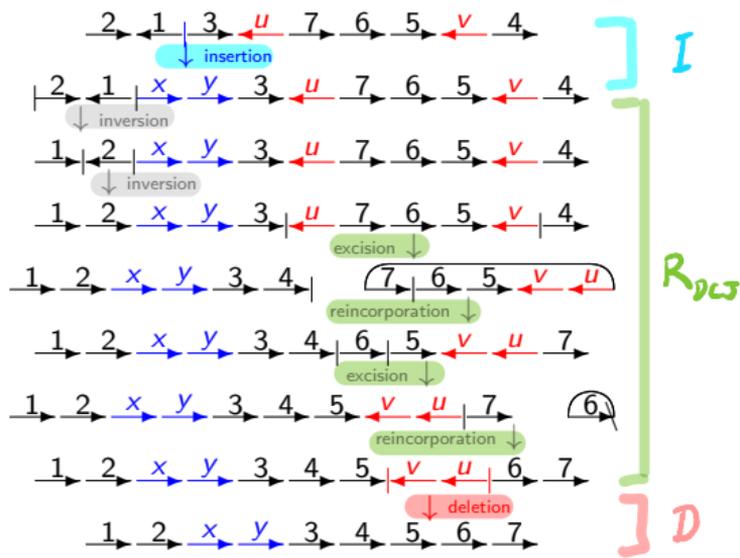

$$S \rightsquigarrow L = I \oplus L_{DCJ} \oplus D \quad \text{and} \quad |S| = |L|$$

# Restricted DCJ-indel-distance (singular linear genomes)

L: "layered" DCJ-indel sorting

R: "layered" **restricted** DCJ-indel sorting

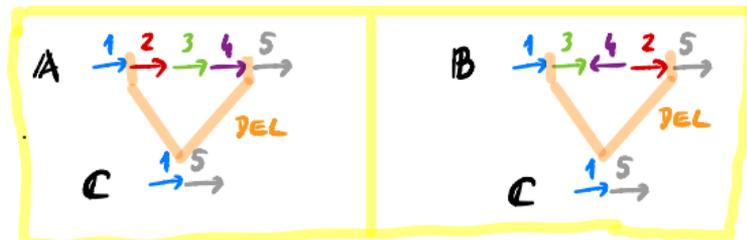

L : "layered" sequence of insertions, DCJs and deletions sorting linear  $\mathbb{A}$  into linear  $\mathbb{B}$

R : "layered" sequence of insertions, restricted DCJs and deletions sorting linear  $\mathbb{A}$  into linear  $\mathbb{B}$

$$S \rightsquigarrow L = I \oplus L_{DCJ} \oplus D \rightsquigarrow R = I \oplus R_{DCJ} \oplus D \quad \text{and} \quad |S| = |S'| = |R|$$

# The triangular inequality does not hold for the DCJ-indel distance

Three singular genomes

$$\begin{cases} \mathbb{A} = [1\ 2\ 3\ 4\ 5] \\ \mathbb{B} = [1\ 3\ \bar{4}\ 2\ 5] \\ \mathbb{C} = [1\ 5] \end{cases}$$

The triangular inequality

$$d_{\text{DCJ}}^{\text{ID}}(\mathbb{A}, \mathbb{B}) \leq d_{\text{DCJ}}^{\text{ID}}(\mathbb{A}, \mathbb{C}) + d_{\text{DCJ}}^{\text{ID}}(\mathbb{B}, \mathbb{C})$$

does not hold

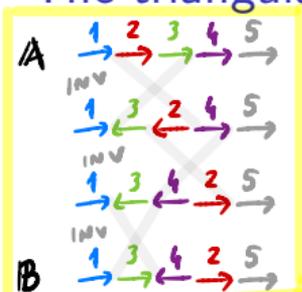

$$\begin{cases} d_{\text{DCJ}}^{\text{ID}}(\mathbb{A}, \mathbb{B}) = 3 \\ d_{\text{DCJ}}^{\text{ID}}(\mathbb{A}, \mathbb{C}) = 1 \\ d_{\text{DCJ}}^{\text{ID}}(\mathbb{B}, \mathbb{C}) = 1 \end{cases}$$

“Free lunch”:  
while sorting  $\mathbb{A}$  into  $\mathbb{C}$  and then  $\mathbb{C}$  into  $\mathbb{B}$ ,  
a set of common genes of  $\mathbb{A}$  and  $\mathbb{B}$   
are deleted and then reinserted

It is possible to define a “corrected” DCJ-indel distance, for which the triangular inequality is fulfilled.

The first step towards this correction is determining the DCJ-indel diameter

# The triangular inequality does not hold for the DCJ-indel distance

Three singular genomes

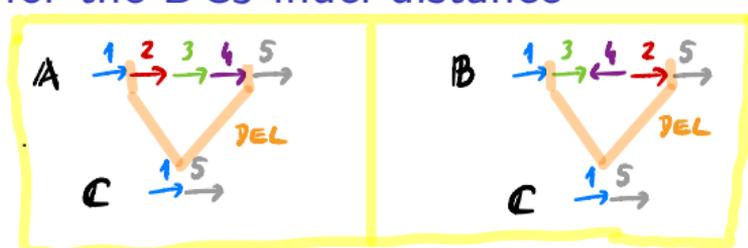

$$\begin{cases} A = [1\ 2\ 3\ 4\ 5] \\ B = [1\ 3\ 4\ 2\ 5] \\ C = [1\ 5] \end{cases}$$

The triangular inequality

$$d_{\text{DCJ}}^{\text{ID}}(A, B) \leq d_{\text{DCJ}}^{\text{ID}}(A, C) + d_{\text{DCJ}}^{\text{ID}}(B, C)$$

does not hold

$$\begin{cases} d_{\text{DCJ}}^{\text{ID}}(A, B) = 3 \\ d_{\text{DCJ}}^{\text{ID}}(A, C) = 1 \\ d_{\text{DCJ}}^{\text{ID}}(B, C) = 1 \end{cases}$$

“Free lunch”:

while sorting A into C and then C into B,  
a set of common genes of A and B  
are deleted and then reinserted

It is possible to define a “corrected” DCJ-indel distance, for which the triangular inequality is fulfilled.

The first step towards this correction is determining the DCJ-indel diameter

OBS: In the comparison of two genomes, the DCJ-indel model prevents the “free lunch”:

common genes cannot be deleted or inserted

# The diameter $D_{DCJ}^{ID}$ of the DCJ-indel-distance

The **diameter** is the tightest known upper bound for a **distance measure**.

Denote by  $D_{DCJ}^{ID}(\mathbb{A}, \mathbb{B})$  the DCJ-indel diameter of two singular genomes  $\mathbb{A}$  and  $\mathbb{B}$ :

$$d_{DCJ}^{ID}(\mathbb{A}, \mathbb{B}) \leq D_{DCJ}^{ID}(\mathbb{A}, \mathbb{B})$$

For determining the diameter  $D_{DCJ}^{ID}(\mathbb{A}, \mathbb{B})$ , we

- ignore path recombinations and consider that the components of  $RG(\mathbb{A}, \mathbb{B})$  are sorted independently
- determine the maximum number of runs that each component of  $RG(\mathbb{A}, \mathbb{B})$  could have

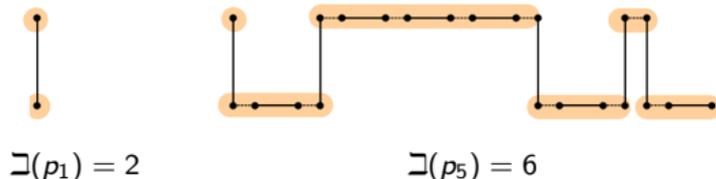

For a given component  $C$  in a relational graph, let a **segment** of  $C$  be

- $C$  itself (if  $C$  is a 0-cycle or a 0-path)
- a minimal path flanked by two extremity-edges
- a minimal path at the extremity of a path and connected to an extremity edge

$\beth(C)$  : number of segments in component  $C$

$\beth(C)$  depends on

- the type of  $C$  (path or cycle)
- the number of extremity edges in  $C$

# Segments of a component in the relational graph

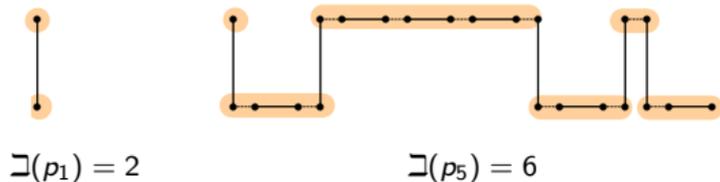

For a given component  $C$  in a relational graph, let a **segment** of  $C$  be

- $C$  itself (if  $C$  is a 0-cycle or a 0-path)
- a minimal path flanked by two extremity-edges
- a minimal path at the extremity of a path and connected to an extremity edge

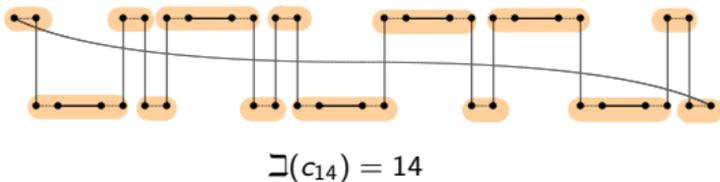

$\beth(C)$  : number of segments in component  $C$

$\beth(C)$  depends on

- the type of  $C$  (path or cycle)
- the number of extremity edges in  $C$

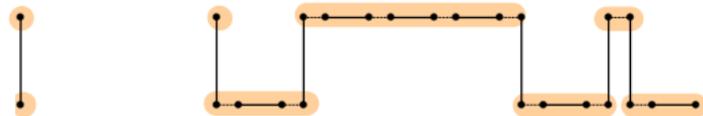

in general  $\left\{ \begin{array}{l} \beth(p_k) = k + 1 \quad k \geq 0 \\ \beth(c_0) = 1 \\ \beth(c_k) = k \quad k \in \{2, 4, 6, \dots\} \end{array} \right.$

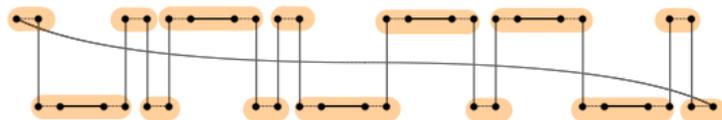

# Segments of a component in the relational graph

$\beth(C)$  : number of segments in component  $C$

$$\beth(p_1) = 2$$

$$\beth(p_5) = 6$$

$$\beth(c_{14}) = 14$$

in general  $\left\{ \begin{array}{l} \beth(p_k) = k + 1 \quad k \geq 0 \\ \beth(c_0) = 1 \\ \beth(c_k) = k \quad k \in \{2, 4, 6, \dots\} \end{array} \right.$

$\Lambda_{\text{MAX}}(C)$  : max. number of runs that  $C$  can have

$\lambda_{\text{MAX}}(C)$  : max. indel-potential that  $C$  can have

$$\Lambda_{\text{MAX}}(C) = \beth(C) \quad \text{and} \quad \lambda_{\text{MAX}}(C) = \left\lceil \frac{\beth(C)+1}{2} \right\rceil$$

$\beth(C)$	$\Lambda_{\text{MAX}}(C)$	$\lambda_{\text{MAX}}(C)$	$d_{\text{DCJ}}(C)$
1	1	1	0
2	2	2	1
3	3	2	1
4	4	3	2
5	5	3	2
6	6	4	2
7	7	4	3
$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\beth(C)$	$\beth(C)$	$\left\lceil \frac{\beth(C)+1}{2} \right\rceil$	$\left\lfloor \frac{\beth(C)-1}{2} \right\rfloor$

# Each component can be sorted separately...

...with an internal gaining DCJ at each step:

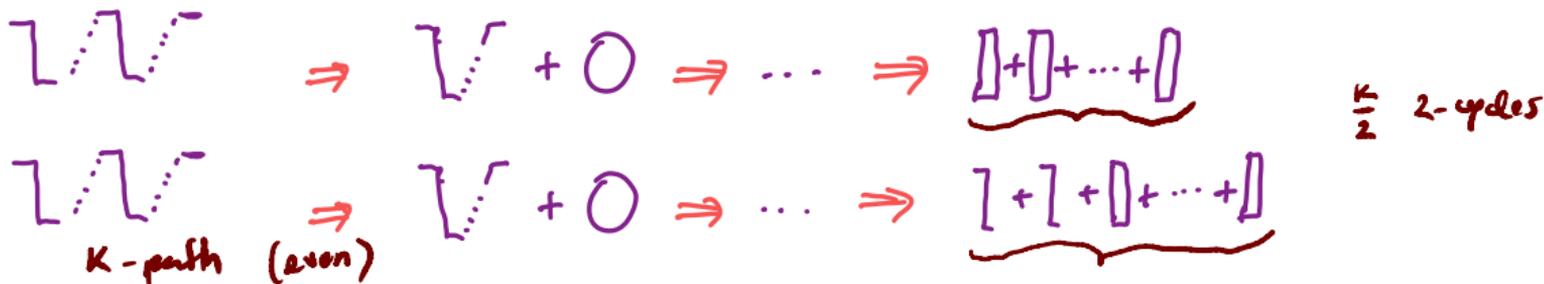

Cycle: creates a new cycle at each step

$\mathbb{A}\mathbb{B}$ -path: creates a new cycle at each step

$\mathbb{A}\mathbb{A}$ -path: creates a new cycle at each step, eventually one step is a single cut (on  $\mathbb{B}$ ) that creates two  $\mathbb{A}\mathbb{B}$ -paths

$\mathbb{B}\mathbb{B}$ -path: analogous to  $\mathbb{A}\mathbb{A}$ -path

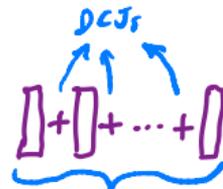

# Each component can be sorted separately...

...with an internal gaining DCJ at each step:

Cycle: creates a new cycle at each step

$k$ -cycle  $\mathcal{J}(C_k) = k$

$\lfloor \frac{k}{2} \rfloor$  2-cycles  
 $\lfloor \frac{k}{2} \rfloor - 1$  DCJs

$\mathbb{A}\mathbb{B}$ -path: creates a new cycle at each step

$k$ -path  $\mathcal{J}(P_k) = k+1$

$\lfloor \frac{k}{2} \rfloor - 1$  2-cycles  
 $\lfloor \frac{k}{2} \rfloor - 1$  DCJs

$\mathbb{A}\mathbb{A}$ -path: creates a new cycle at each step, eventually one step is a single cut (on  $\mathbb{B}$ ) that creates two  $\mathbb{A}\mathbb{B}$ -paths

$\lfloor \frac{k-1}{2} \rfloor$  2-cycles

$\lfloor \frac{k-1}{2} \rfloor$  DCJs

$k$ -path  $\mathcal{J}(P_k) = k+1$

$\mathbb{B}\mathbb{B}$ -path: analogous to  $\mathbb{A}\mathbb{A}$ -path

$$\mathcal{L}_{DCJ}(C) = \left\lfloor \frac{\mathcal{J}(C) - 1}{2} \right\rfloor$$

# The diameter $D_{DCJ}^{ID}$ of the DCJ-indel-distance

$\beth(C)$  : number of segments in component  $C$

$\beth(C)$	$\Lambda_{MAX}(C)$	$\lambda_{MAX}(C)$	$d_{DCJ}(C)$
1	1	1	0
2	2	2	0
3	3	2	1
4	4	3	1
5	5	3	2
6	6	4	2
7	7	4	3
$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\beth(C)$	$\beth(C)$	$\lceil \frac{\beth(C)+1}{2} \rceil$	$\lfloor \frac{\beth(C)-1}{2} \rfloor$

if  $\beth(C)$  is odd:

$$d_{DCJ}(C) + \lambda_{MAX}(C) = \frac{\beth(C)-1}{2} + \frac{\beth(C)+1}{2} = \beth(C)$$

if  $\beth(C)$  is even:

$$d_{DCJ}(C) + \lambda_{MAX}(C) = \frac{\beth(C)-2}{2} + \frac{\beth(C)+2}{2} = \beth(C)$$

$$\text{Let } \begin{cases} \kappa(\mathbb{A}) : \# \text{ linear chromosomes in } \mathbb{A} \\ \mathcal{S}(\mathbb{A}) : \# \text{ (circular) singletons in } \mathbb{A} \\ \kappa(\mathbb{B}) : \# \text{ linear chromosomes in } \mathbb{B} \\ \mathcal{S}(\mathbb{B}) : \# \text{ (circular) singletons in } \mathbb{B} \end{cases}$$

The number of segments in  $RG(\mathbb{A}, \mathbb{B})$  is

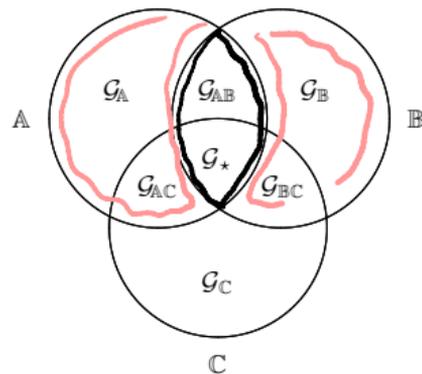

$$\beth(RG(\mathbb{A}, \mathbb{B})) = 2n + \kappa(\mathbb{A}) + \mathcal{S}(\mathbb{A}) + \kappa(\mathbb{B}) + \mathcal{S}(\mathbb{B})$$

$$\begin{aligned} D_{DCJ}^{ID}(\mathbb{A}, \mathbb{B}) &= \sum_{C \in RG(\mathbb{A}, \mathbb{B})} (d_{DCJ}(C) + \lambda_{MAX}(C)) \\ &= \sum_{C \in RG(\mathbb{A}, \mathbb{B})} \beth(C) \\ &= \beth(RG(\mathbb{A}, \mathbb{B})) \end{aligned}$$

$$D_{DCJ}^{ID}(\mathbb{A}, \mathbb{B}) = 2n + \kappa(\mathbb{A}) + \mathcal{S}(\mathbb{A}) + \kappa(\mathbb{B}) + \mathcal{S}(\mathbb{B})$$

# Establishing the triangular inequality

Disjoint sets of genes  $\mathcal{G}_A$ ,  $\mathcal{G}_B$ ,  $\mathcal{G}_C$ ,  $\mathcal{G}_{AB}$ ,  $\mathcal{G}_{BC}$ ,  $\mathcal{G}_{AC}$  and  $\mathcal{G}_*$   
for three genomes A, B and C

For each pair of genomes, we define the **corrected distance**  $dk_{DCJ}^{ID}$ :

$$dk_{DCJ}^{ID}(A, B) = d_{DCJ}^{ID}(A, B) + k(|\mathcal{G}_A| + |\mathcal{G}_{AC}| + |\mathcal{G}_B| + |\mathcal{G}_{BC}|)$$

$$dk_{DCJ}^{ID}(A, C) = d_{DCJ}^{ID}(A, C) + k(|\mathcal{G}_A| + |\mathcal{G}_{AB}| + |\mathcal{G}_C| + |\mathcal{G}_{BC}|)$$

$$dk_{DCJ}^{ID}(B, C) = d_{DCJ}^{ID}(B, C) + k(|\mathcal{G}_B| + |\mathcal{G}_{AB}| + |\mathcal{G}_C| + |\mathcal{G}_{AC}|)$$

The triangular inequality must hold for  $dk_{DCJ}^{ID}$ :

$$dk_{DCJ}^{ID}(A, B) \leq dk_{DCJ}^{ID}(A, C) + dk_{DCJ}^{ID}(B, C)$$

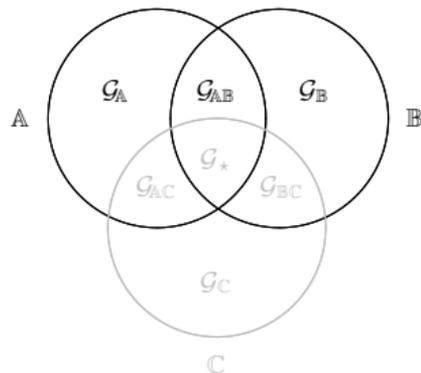

$$d_{DCJ}^{ID}(A, B) + k(\cancel{|\mathcal{G}_A|} + |\mathcal{G}_{AC}| + |\mathcal{G}_B| + \cancel{|\mathcal{G}_{BC}|}) \leq d_{DCJ}^{ID}(A, C) + k(\cancel{|\mathcal{G}_A|} + |\mathcal{G}_{AB}| + |\mathcal{G}_C| + \cancel{|\mathcal{G}_{BC}|}) + d_{DCJ}^{ID}(B, C) + k(\cancel{|\mathcal{G}_B|} + |\mathcal{G}_{AB}| + |\mathcal{G}_C| + \cancel{|\mathcal{G}_{AC}|})$$

$$d_{DCJ}^{ID}(A, B) \leq d_{DCJ}^{ID}(A, C) + k(|\mathcal{G}_{AB}| + |\mathcal{G}_C|) + d_{DCJ}^{ID}(B, C) + k(|\mathcal{G}_{AB}| + |\mathcal{G}_C|)$$

$$d_{DCJ}^{ID}(A, B) \leq d_{DCJ}^{ID}(A, C) + d_{DCJ}^{ID}(B, C) + 2k(|\mathcal{G}_{AB}| + |\mathcal{G}_C|)$$

# Establishing the triangular inequality

$$\begin{cases} d_{DCJ}^{ID}(A, B) \leq d_{DCJ}^{ID}(A, C) + d_{DCJ}^{ID}(B, C) + 2k(|\mathcal{G}_{AB}| + |\mathcal{G}_C|) \\ d_{DCJ}^{ID}(A, C) \leq d_{DCJ}^{ID}(A, B) + d_{DCJ}^{ID}(B, C) + 2k(|\mathcal{G}_{AC}| + |\mathcal{G}_B|) \\ d_{DCJ}^{ID}(B, C) \leq d_{DCJ}^{ID}(A, B) + d_{DCJ}^{ID}(A, C) + 2k(|\mathcal{G}_{BC}| + |\mathcal{G}_A|) \end{cases}$$

Assume  $\begin{cases} d_{DCJ}^{ID}(A, B) \geq d_{DCJ}^{ID}(A, C) \\ d_{DCJ}^{ID}(A, B) \geq d_{DCJ}^{ID}(B, C) \end{cases}$  Let  $\begin{cases} \chi(A): \# \text{ chromosomes in } A \\ \kappa(A): \# \text{ linear chromosomes in } A \\ \mathcal{S}(A): \# \text{ (circular) singletons in } A \\ \chi(B): \# \text{ chromosomes in } B \\ \kappa(B): \# \text{ linear chromosomes in } B \\ \mathcal{S}(B): \# \text{ (circular) singletons in } B \end{cases}$   $\begin{cases} \kappa(A) + \mathcal{S}(A) \leq \chi(A) \\ \kappa(B) + \mathcal{S}(B) \leq \chi(B) \end{cases}$  and

We need to find a value  $k$  that guarantees:

$$d_{DCJ}^{ID}(A, B) \leq d_{DCJ}^{ID}(A, C) + d_{DCJ}^{ID}(B, C) + 2k(|\mathcal{G}_{AB}| + |\mathcal{G}_C|)$$

$$D_{DCJ}^{ID}(A, B) \leq \chi(A) + \chi(B) + 2k|\mathcal{G}_{AB}|$$

⋮

In the worst case genome  $C$  is empty:

$$d_{DCJ}^{ID}(A, C) = \chi(A) \quad \text{and} \quad d_{DCJ}^{ID}(B, C) = \chi(B)$$

$$2|\mathcal{G}_{AB}| \leq 2k|\mathcal{G}_{AB}| \Rightarrow \boxed{k \geq 1}$$

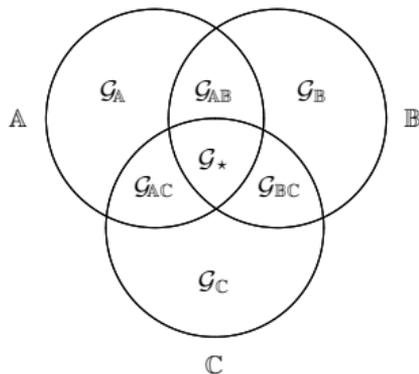

$$D_{DCJ}^{ID}(A, B) = 2|\mathcal{G}_{AB}| + \kappa(A) + \mathcal{S}(A) + \kappa(B) + \mathcal{S}(B)$$

## Establishing the triangular inequality

$$dk_{DCJ}^{ID}(A, B) = d_{DCJ}^{ID}(A, B) + k(|\mathcal{G}_A| + |\mathcal{G}_{AC}| + |\mathcal{G}_B| + |\mathcal{G}_{BC}|)$$

$$dk_{DCJ}^{ID}(A, C) = d_{DCJ}^{ID}(A, C) + k(|\mathcal{G}_A| + |\mathcal{G}_{AB}| + |\mathcal{G}_C| + |\mathcal{G}_{BC}|)$$

$$dk_{DCJ}^{ID}(B, C) = d_{DCJ}^{ID}(B, C) + k(|\mathcal{G}_B| + |\mathcal{G}_{AB}| + |\mathcal{G}_C| + |\mathcal{G}_{AC}|)$$

The triangular inequality holds for the corrected distance  $dk_{DCJ}^{ID}$  for any  $k \geq 1$

# Quiz 1

1 Which of the following statements about the DCJ-indel model are true?

~~A~~

The triangular inequality holds for the DCJ-indel distance.

B

The triangular inequality does not hold for the DCJ-indel distance, but a simple correction can be done.

~~C~~

The DCJ-indel distance can be distinct from the restricted DCJ-indel distance.

2 The best known algorithm for the restricted DCJ-indel sorting runs in...

A  $O(n)$  time.

B

$O(n \log n)$  time.

C  $O(n^2)$  time.

# Capped relational graph

Capping is a procedure that circularizes all paths of a relational graph by adding **caps (artificial genes)**:

- ▶ if the capping is optimal, the genomic distance is preserved
- ▶ from the capped relational diagram we can derive genomes composed only of circular chromosomes

A capping may require adjacencies between caps:

$\Gamma_{\mathbb{A}}$ : represents an adjacency between caps in genome  $\mathbb{A}$

$\Gamma_{\mathbb{B}}$ : represents an adjacency between caps in genome  $\mathbb{B}$ .

# Capped relational graph of canonical genomes

Optimally linking paths from  $RG(\mathbb{A}, \mathbb{B})$  of canonical genomes  $\mathbb{A}$  and  $\mathbb{B}$  into cycles can be done as follows:

id	paths	linking cycle		$\Delta n$	$\Delta c$	$\Delta(2\mathbb{A}\mathbb{B})$	$\Delta_{\text{DCJ}}$
1	$\mathbb{A}\mathbb{B}$	$(\mathbb{A}\mathbb{B})$		+0.5	+1	-0.5	0
2	$\mathbb{A}\mathbb{A} + \mathbb{B}\mathbb{B}$	$(\mathbb{A}\mathbb{A}, \mathbb{B}\mathbb{B})$		+1	+1	0	0
3	$\mathbb{A}\mathbb{A}$	$(\mathbb{A}\mathbb{A}, \Gamma_{\mathbb{B}})$	$\cup$	+1	+1	0	0
4	$\mathbb{B}\mathbb{B}$	$(\mathbb{B}\mathbb{B}, \Gamma_{\mathbb{A}})$	$\cap$	+1	+1	0	0

- { Closing an  $\mathbb{A}\mathbb{A}$ -path (over-represented in genome  $\mathbb{A}$  and marked with a  $\cup$ ) requires an adjacency  $\Gamma_{\mathbb{B}}$ .
- { Closing a  $\mathbb{B}\mathbb{B}$ -path (over-represented in genome  $\mathbb{B}$  and marked with a  $\cap$ ) requires an adjacency  $\Gamma_{\mathbb{A}}$ .

Any capping producing linking cycles as indicated on the table above is optimal:

- ▶ The value  $\Delta_{\text{DCJ}} = \Delta n - \Delta c - \Delta(2\mathbb{A}\mathbb{B})$  is the DCJ-effect produced by each type of linking cycle.
- ▶ All given linking cycles have  $\Delta_{\text{DCJ}} = 0$ , therefore they preserve the DCJ distance.

Let  $\begin{cases} \kappa_{\mathbb{A}}: \text{number of linear chromosomes in } \mathbb{A} \\ \kappa_{\mathbb{B}}: \text{number of linear chromosomes in } \mathbb{B} \end{cases}$

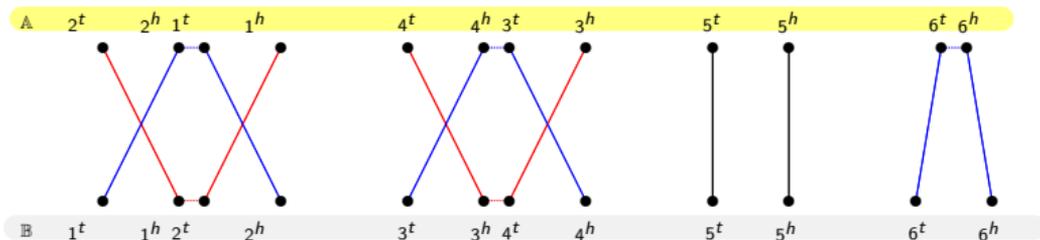

The difference between the number of  $\mathbb{A}\mathbb{A}$ - and of  $\mathbb{B}\mathbb{B}$ -paths is equal to the difference between  $\kappa_{\mathbb{A}}$  and  $\kappa_{\mathbb{B}}$ .

An optimal capping that maximizes the number of linking cycles of type **2** minimizes the number of caps:

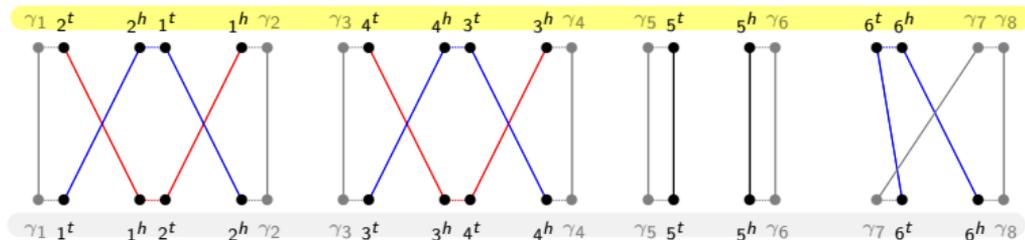

- { The number of caps to be added is exactly  $p_* = \max\{\kappa_{\mathbb{A}}, \kappa_{\mathbb{B}}\}$ .
- { The number of adjacencies between caps is exactly  $a_* = |\kappa_{\mathbb{A}} - \kappa_{\mathbb{B}}|$ .

# Capped relational graph of canonical genomes - example

$$\mathbb{A} = [2^t \ 1^h] [4^t \ 3^h] [5^t] (6) \quad \text{and} \quad \mathbb{B} = [1^t \ 2^h] [3^t \ 4^h] [5^t] [6^h] \quad ; \quad p_* = 4 \quad \text{and} \quad a_* = 1$$

$$\begin{aligned} d_{\text{DCJ}} &= n - |\mathcal{C}| - \frac{|\mathcal{P}_{\mathbb{A}\mathbb{B}}|}{2} \\ &= 6 - 0 - 1 \\ &= 5 \end{aligned}$$

$$\begin{aligned} d_{\text{DCJ}} &= n + p_* - |\mathcal{C}| \\ &= 6 + 4 - 5 \\ &= 5 \end{aligned}$$

Any way of pairing the cap extremities  $\gamma_1, \gamma_2, \dots, \gamma_8$  is valid; possible derived circular genomes are:

$$\mathbb{A}_o = (2 \ 1 \ W) (4 \ 3 \ X) (5 \ Y) (6) (Z) \quad \text{and} \quad \mathbb{B}_o = (1 \ 2 \ W) (3 \ 4 \ X) (5 \ Y) (6 \ Z)$$

$$(W^h = \gamma_1, W^t = \gamma_2, X^h = \gamma_3, X^t = \gamma_4, Y^h = \gamma_5, Y^t = \gamma_6, Z^h = \gamma_7, Z^t = \gamma_8)$$

or

$$\mathbb{A}_o = (2 \ 1 \ W \ 4 \ 3 \ X \ 5 \ Y \ Z) (6) \quad \text{and} \quad \mathbb{B}_o = (1 \ 2 \ W \ 3 \ 4 \ X \ 5 \ Y \ 6 \ Z)$$

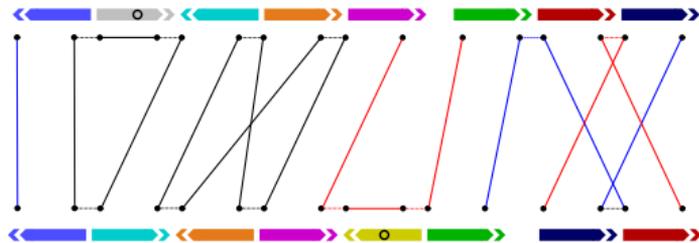

$$(W^h = \gamma_3, W^t = \gamma_2, X^h = \gamma_5, X^t = \gamma_4, Y^h = \gamma_7, Y^t = \gamma_6, Z^h = \gamma_1, Z^t = \gamma_8)$$

# Capped relational graph

$n = \#$  common families

$$p_* = \max \begin{cases} \# \text{ linear chromosomes in } A \\ \# \text{ linear chromosomes in } B \end{cases}$$

$$n = 7, \quad p_* = 3$$

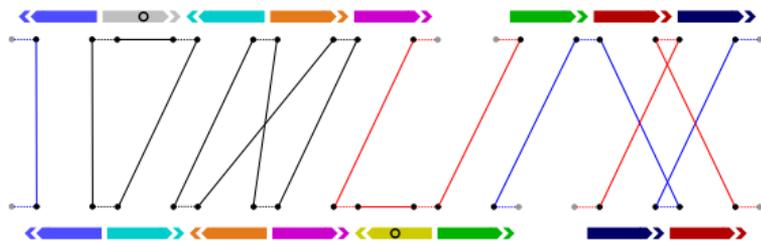

# Capped relational graph

$n = \#$  common families

$$p_* = \max \begin{cases} \# \text{ linear chromosomes in } A \\ \# \text{ linear chromosomes in } B \end{cases}$$

$n = 7$  ,  $p_* = 3$   
6 cap vertices per genome

add  $2p_*$  cap vertices to each genome

each cap is connected by an adjacency edge  
to the end of a path

{ if  $\#$  linear chromosomes is different, connect  
each pair of isolated caps with an adjacency edge

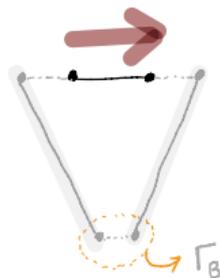

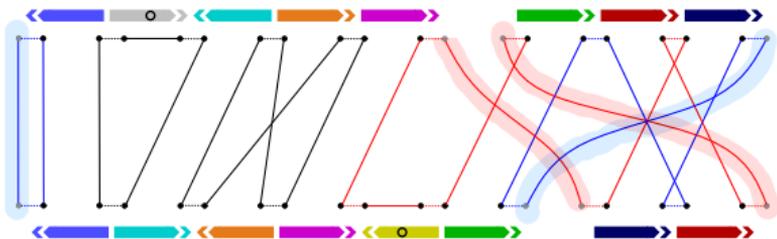

$\Gamma_A$ : represents an adjacency between caps in A  
 $\Gamma_B$ : represents an adjacency between caps in B

# Capped relational graph

$n = \#$  common families

$$p_* = \max \begin{cases} \# \text{ linear chromosomes in } A \\ \# \text{ linear chromosomes in } B \end{cases}$$

$n = 7$  ,  $p_* = 3$   
6 cap vertices per genome

add  $2p_*$  cap vertices to each genome

each cap is connected by an adjacency edge  
to the end of a path

link each cap from A to a cap from B: only cycles

{ if  $\#$  linear chromosomes is different, connect  
each pair of isolated caps with an adjacency edge

$\Gamma_A$ : represents an adjacency between caps in A  
 $\Gamma_B$ : represents an adjacency between caps in B

## DCJ-optimal capping

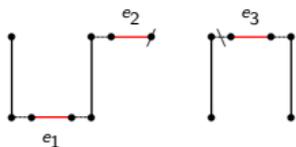

paths	linking cycle	$\Delta n$	$\Delta  C $	$\Delta(2 \mathcal{P}_{AB} )$	$\Delta_{DCJ}$
AB	(AB)	+0.5	+1	-0.5	0
AA + BB	(AA, BB)	+1	+1	0	0
AA	(AA, $\Gamma_B$ )	+1	+1	0	0
BB	(BB, $\Gamma_A$ )	+1	+1	0	0

{ Closing an AA-path requires an adjacency  $\Gamma_B$ .  
Closing a BB-path requires an adjacency  $\Gamma_A$ .

# Capped relational graph of singular genomes - example

The four sources of a chain of deducing recombinations are optimally linked into a single cycle.

# Capped relational graph of singular genomes

The sources of each chain of deducing recombinations must be properly linked together into a single cycle.

- Unbalanced chains over-represented in genome  $\mathbb{A}$  are marked with a  $\cup$ 
  - $\mathbb{B}\mathbb{B}_\epsilon \prec \Gamma_{\mathbb{B}}$ : a path  $\mathbb{B}\mathbb{B}_\epsilon$  is preferred to close a  $\cup$ -unbalanced chain; if it does not exist, an adjacency  $\Gamma_{\mathbb{B}}$  is used
- Unbalanced chains over-represented in genome  $\mathbb{B}$  are marked with a  $\cap$ 
  - $\mathbb{A}\mathbb{A}_\epsilon \prec \Gamma_{\mathbb{A}}$ : a path  $\mathbb{A}\mathbb{A}_\epsilon$  is preferred to close a  $\cap$ -unbalanced chain; if it does not exist, an adjacency  $\Gamma_{\mathbb{A}}$  is used

In order to give the correct order of linking  $\left\{ \begin{array}{l} \text{a path } \mathbb{A}\mathbb{B}_{\mathbb{A}\mathbb{B}} \text{ can be represented by } \mathbb{B}\mathbb{A}_{\mathbb{B}\mathbb{A}} \\ \text{a path } \mathbb{A}\mathbb{B}_{\mathbb{B}\mathbb{A}} \text{ can be represented by } \mathbb{B}\mathbb{A}_{\mathbb{A}\mathbb{B}} \end{array} \right.$

DCJ-  
indel  
optimal  
capping

	remaining paths	linking cycle		$\Delta n$	$\Delta c$	$\Delta(2\mathbb{A}\mathbb{B})$	$\Delta\lambda$	$\Delta_{DCJ}^\lambda$
1	$\mathbb{A}\mathbb{B}_*$	$(\mathbb{A}\mathbb{B}_*)$		+0.5	+1	-0.5	0	0
2	$\mathbb{A}\mathbb{A}_* + \mathbb{B}\mathbb{B}_*$	$(\mathbb{A}\mathbb{A}_*, \mathbb{B}\mathbb{B}_*)$		+1	+1	0	0	0
3	$\mathbb{A}\mathbb{A}_*$	$(\mathbb{A}\mathbb{A}_*, \Gamma_{\mathbb{B}})$	$\cup$	+1	+1	0	0	0
4	$\mathbb{B}\mathbb{B}_*$	$(\mathbb{B}\mathbb{B}_*, \Gamma_{\mathbb{A}})$	$\cap$	+1	+1	0	0	0

Any capping producing linking cycles following a top-down screening of the table above is optimal:

- ▶  $\Delta_{DCJ}^\lambda = \Delta n - \Delta c - \Delta(2\mathbb{A}\mathbb{B}) + \Delta\lambda$  gives the DCJ-indel-effect produced by each type of linking cycle.
- ▶ All given linking cycles have  $\Delta_{DCJ}^\lambda$  equivalent to the respective chain of deducing recombinations, therefore they achieve the optimal DCJ-indel distance.

**P1:** After identifying chains of recombinations  $\left\{ \begin{array}{l} \text{either there are no unbalanced chains} \\ \text{or there are only } \cup\text{-unbalanced chains (over-repr. in } \mathbb{A}) \\ \text{or there are only } \cap\text{-unbalanced chains (over-repr. in } \mathbb{B}) \end{array} \right.$

**P2:** When an unbalanced chain is being linked

$\left\{ \begin{array}{l} \text{if there is a remaining indel-free } \mathbb{A}\mathbb{A}_\varepsilon/\mathbb{B}\mathbb{B}_\varepsilon \text{ (of the under-repr. genome), it is used to link the chain} \\ \text{otherwise there is no remaining } \mathbb{A}\mathbb{A}_*/\mathbb{B}\mathbb{B}_* \text{ (of the under-repr. genome) and an adjacency } \Gamma_{\mathbb{A}/\mathbb{B}} \text{ links the chain} \end{array} \right.$

Any optimal capping that links all possible chains of deducing recombinations as described above and, for the remaining paths, maximizes the number of linking cycles of type 2 minimizes the number of caps:

$\left\{ \begin{array}{l} \text{The number of caps to be added is exactly } p_* = \max\{\kappa_{\mathbb{A}}, \kappa_{\mathbb{B}}\}. \\ \text{The number of adjacencies between caps is exactly } a_* = |\kappa_{\mathbb{A}} - \kappa_{\mathbb{B}}|. \end{array} \right.$

# Quiz 2

1 Which of the following statements about the capped relational graph are true?

- A In an optimal capping, the distance computed based on the capped relational diagram must be equivalent to the distance computed based on the original relational diagram.
- B Let  $RG(\mathbb{A}, \mathbb{B})$  be a relational graph of **canonical** genomes.  
An optimal capping of  $RG(\mathbb{A}, \mathbb{B})$  that maximizes the number of cycles linking a pair  $\mathbb{A}\mathbb{A} + \mathbb{B}\mathbb{B}$  has a minimum number of caps ( $= \max\{\kappa_{\mathbb{A}}, \kappa_{\mathbb{B}}\}$ ).
- C Let  $\max\{\kappa_{\mathbb{A}_s}, \kappa_{\mathbb{B}_s}\} = \max\{\kappa_{\mathbb{A}_c}, \kappa_{\mathbb{B}_c}\}$ .  
An optimal capping of the relational graph of **singular** genomes  $\mathbb{A}_s$  and  $\mathbb{B}_s$  requires more caps than an optimal capping of the relational graph of **canonical** genomes  $\mathbb{A}_c$  and  $\mathbb{B}_c$ .
- D The indel-potential can be equivalently computed based on the number of runs or based on the number of transitions.
