Exercises

Number 8, Discussion: 2024 January 12

1. Given a list of peaks from a Tandem Mass Spectrum (MS/MS) for peptide de-novo sequencing, one important obstacle for recovering the peptide sequence is to assign peaks to the main ion types b and y (prefix and suffix strings of the peptide sequence, respectively).

If we know that only b -ions are present in the spectrum, then recovering the sequence becomes simple. Describe an algorithm to do so: Input are the parent mass W and an ordered list of prefix masses w_1, \dots, w_k . (Some peaks may be missing, though.)

2. We modify the above problem such that there are “noise peaks” (of unknown origin) in the mass spectrum. Describe an algorithm that finds a peptide sequence maximizing the number of explained peaks. The algorithm should run in $O(k|\Sigma|)$ time where k is the number of peaks and Σ is the underlying alphabet of amino acids. Hint: Use dynamic programming.

3. Word puzzling:

- How many different words can be built by using all the letters of the string $S = \text{GLÜHWEIN}$ exactly once? Compute the actual value.
- How many different words can be built by using all the letters of the string $S = \text{TEELICHT}$ exactly once? Note that all words need to have the same length and must use the letters the specified number of times: For ABA , there are three such words, AAB , ABA , BAA .
- Try and find a general formula for the number of different words $\text{wordnum}(S)$ that can be created from the letters of a string S . Hint: For $S = \text{ALGORITHMUS}$, the formula depends only on the length of S , but not for $S = \text{ABRACADABRA}$ - what else does it depend on?

4. Suppose that we do not know the order of characters in a string: For example, the strings AACCC , ACACC , \dots , CCCAA are indistinguishable to us. We call such “strings without order” *compomers* (denoted A_2C_3 for our example). The *length* of a compomer is the length of the corresponding string (5 in our example).

- Let $\Sigma = \{\text{A}, \text{C}, \text{G}, \text{T}\}$ be our alphabet, then there exist 4 compomers of length 1 ($\text{A}_1, \text{C}_1, \text{G}_1, \text{T}_1$) and 10 compomers of length 2 ($\text{A}_2, \text{A}_1\text{C}_1, \text{A}_1\text{G}_1, \text{A}_1\text{T}_1, \text{C}_2, \text{C}_1\text{G}_1, \text{C}_1\text{T}_1, \text{G}_2, \text{G}_1\text{T}_1, \text{T}_2$). How many compomers exist of lengths 3 and 4?
- Derive a general formula for the number of compomers of length n over an arbitrary alphabet Σ of size σ .
